Bootstrapping + Regression, pt. 1

Philip Waggoner, MACS 30100 University of Chicago

Overview

Today:

- 1. Bootstrapping (uncertainty around mean and β)
- 2. Basic regression modeling in R (fitting, interpreting, plotting, and conditional relationships)

The Bootstrap

Task: how often Americans eat ice cream in a given month.

Sub-task: check distributional assumptions of the likely distribution of these data: Poisson distribution The probability mass function (PMF) for the Poisson distribution,

$$\Pr(X = x) = e^{-\lambda} \frac{\lambda^k}{k!},$$

where λ is the event rate, e is Euler's number, k is an integer with range $[0, \infty]$.

Bootstrapping (from lecture):

- 1. Draw B samples with replacement from the sample (of size N)
- 2. (For our task) calculate the mean of the bootstrapped sample means $\hat{\mu}_1, \hat{\mu}_2, \dots, \hat{\mu}_B$ 3. Estimate the standard error (SE) of the sample mean $\hat{\mu}$, $SE_B(\hat{\mu}) = \sqrt{\frac{1}{B-1} \sum_{r=1}^B \left(\hat{\mu}_r \frac{1}{B} \sum_{r'=1}^B \hat{\mu}_{r'}\right)^2}$

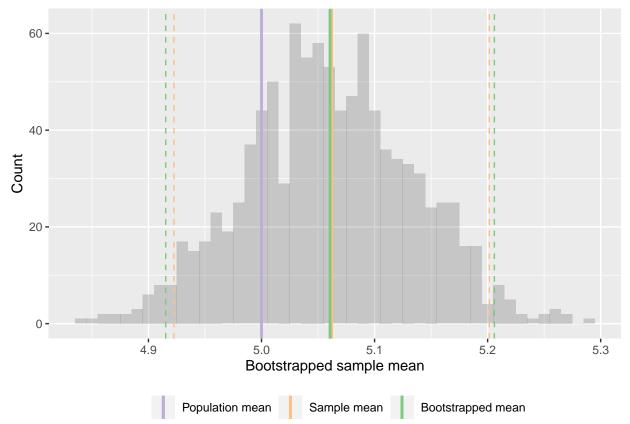

Application

Let's see this in action.

```
library(tidyverse)
## -- Attaching packages ----- tidyverse 1.3.0 --

```

Causal direction

Exploring the first difference over party affiliation.

Expected Obama thermometer score

On your own

For this section, you will work in small groups of 4-5. I will create these groups at random.

IMPORTANT: Don't forget that this code you're working on here is due at the appropriate Canvas module (in the form of an attachment to a "Discussion" post) prior to 5:00 pm CDT tomorrow. You need only submit a **single** file/script to be considered for credit (i.e., this .Rmd with your code inserted below each question). Recall, I don't care whether you got things right. I only care that attempts to each question have

been made.

Biden feelings data from the ANES. Load with the following code.

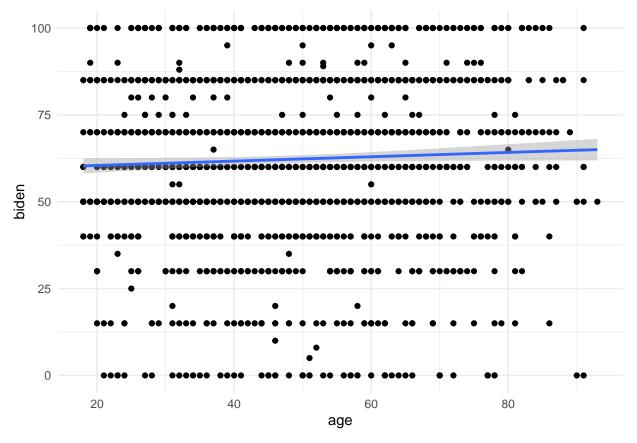

```
library(tidyverse)
library(broom)
library(here)
biden <- read_csv(here("data", "biden.csv"))</pre>
##
## -- Column specification -----
## cols(
##
    biden = col_double(),
    female = col_double(),
##
##
    age = col_double(),
    educ = col_double(),
##
##
    dem = col_double(),
    rep = col_double()
##
## )
#view(biden)
```

1. Estimate a linear model of the relationship between age (age) and attitudes toward Biden (biden), and plot the results. Remember to show the 95% confidence interval around your estimated fit line (hint: geom_smooth()). For reference, this simple model takes the form,

```
Biden_i = \beta_0 + \beta_1 Age
```

```
biden_age_lm <- lm(biden ~ poly(age, 1, raw = TRUE), data = biden); tidy(biden_age_lm)
## # A tibble: 2 x 5
##
    term
                              estimate std.error statistic
                                                             p.value
##
     <chr>
                                           <dbl>
                                                     <dbl>
                                                     35.9 1.15e-213
## 1 (Intercept)
                               59.2
                                          1.65
## 2 poly(age, 1, raw = TRUE)
                              0.0624
                                          0.0327
                                                      1.91 5.63e- 2
ggplot(biden, aes(age, biden)) +
  geom_point() +
  geom_smooth(method = "lm") +
 theme_minimal()
```

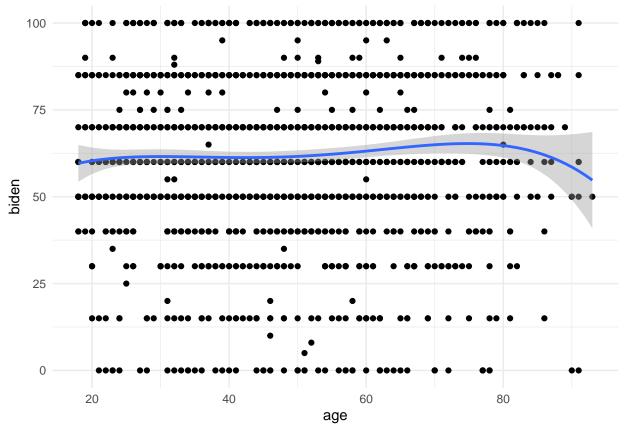

`geom_smooth()` using formula 'y ~ x'

2. Relax the linear assumption to attempt to account for the fewer observations at the extreme values of age, and estimate a fourth-order polynomial regression of the relationship between age and attitudes towards Biden (that is, wrap X's in poly()), and plot the results. Again, remember to show the 95% confidence interval around your estimated fit line. For reference, the fourth-order polynomial model takes the form,

$$\mathrm{Biden}_i = \beta_0 + \beta_1 \mathrm{Age} + \beta_2 \mathrm{Age}^2 + \beta_3 \mathrm{Age}^3 + \beta_4 \mathrm{Age}^4$$

```
biden_4_order_lm <- lm(biden ~ poly(age, 4, raw = TRUE), data = biden); tidy(biden_4_order_lm)
## # A tibble: 5 x 5
##
     term
                                   estimate
                                              std.error statistic p.value
##
     <chr>>
                                      <dbl>
                                                   <dbl>
                                                             <dbl>
                                                                      <dbl>
## 1 (Intercept)
                                37.5
                                            24.9
                                                              1.50
                                                                     0.133
## 2 poly(age, 4, raw = TRUE)1 2.37
                                             2.28
                                                              1.04
                                                                     0.299
## 3 poly(age, 4, raw = TRUE)2 -0.0833

- 3. In the figure produced in response to the previous question, you plotted the predicted values with the 95% confidence interval. In the case of ordinary linear regression (both the simple and polynomial models in our case), this is easy to estimate. Recall, the **standard error** is a measure of variance for the estimated parameter and is calculated by taking the square root (sqrt()) of the diagonal (diag()) of the variance-covariance matrix (vcov()). Standard errors, which are simply measures of uncertainty around some estimate, are critical to a traditional understanding of "statistical significance," which is reached by diagnosing t-statistics. Of note, t-statistics can be calculated by dividing estimated coefficients (\$coefficients) by their standard errors. So assuming errors are t-distributed, if these values are greater than 1.96 (the so-called "t-critical value for 95% confidence"), then the estimate is assumed to be "significant" at the 95% confidence level (note: t >≈ 2.5 for significance at 99% level).
 - Obtain the variance-covariance matrix for your polynomial regression, and then calculate (by hand/don't call values from broom::tidy()) and report the standard errors for each parameter from your polynomial regression (to answer this, make sure you read the question carefully).
